# Can bulk longshore and/or cross-shore transport equations be used to predict deflation rates of sediment placed in the nearshore?

- Existing predictive methods tend to emphasize the likelihood of sediment motion, but they do not calculate the rate of sediment removal from a placement site
  - e.g., McLellan *et al.* (1990), Hands and Allison (1991), Ahrens and Hands (1998); McFall *et al.* (2016); Priestas *et al.* (2019)
- Recent progress towards cross-shore deflation rate prediction by Hudson *et al.* (2021).
- Objective is to develop a computationally-efficient method of generating order-of-magnitude nearshore berm deflation rates using combined longshore and cross-shore transport equations.

## Statements of Need:

- 2020-N-1564: Increasing Beach Nourishment Lifespan with Nearshore Nourishments
- 2020-N-1481: Improving scoping level estimates of the lifespans and deflation rates of nearshore nourishments
- 2019-N-1386 Strategic Nearshore Placement of Dredged Material to Sustain Coastal Beach & Dune Resilience
- 2017-N-70 Analysis of Shoreline Response to Nearshore Placement Geometry
- 2016-N-04 Quantifying wave and current driven sediment transport at nearshore dredge disposal sites

# Capability and Strategic Impact Statement

An algorithm for estimating nearshore berm deflation rates using published longshore and cross-shore transport equations will provide valuable information for placement design and re-nourishment planning.

The algorithm will be implemented within the Sediment Mobility Tool to facilitate usage.

## Sediment Mobility Tool (SMT)

Sediment Mobility Tool (SMT)—Scoping-level tool that displays Depth of Closure (DoC) and sediment mobility data for the US coastline to help in determining how best to use dredged sediment and where to site nearshore placement areas. Click [help](#) for additional details.

1. Scroll to the appropriate location. 2. Draw Shoreline Angle 3. Select Placement Site Or Latitude:  Longitude:  4. Find WIS / Calculate Angle

Shoreline Angle: 238° Closest WIS ID: 73046

5. User Inputs.

$d_{50}$   mm Nearshore Placement Depth  m Current 1m (~3ft) above the bed  m/s Temperature  °F Salinity  psu

# Algorithm overview

- Longshore and cross-shore transport rates are independently calculated and then superimposed to generate a total deflation rate.
- Parameters include nearshore berm position, geometry, and grain size, along with wave height, direction, and period from the most proximal WIS station.
- Percentage of longshore transport contributing to deflation is based on experimental data.

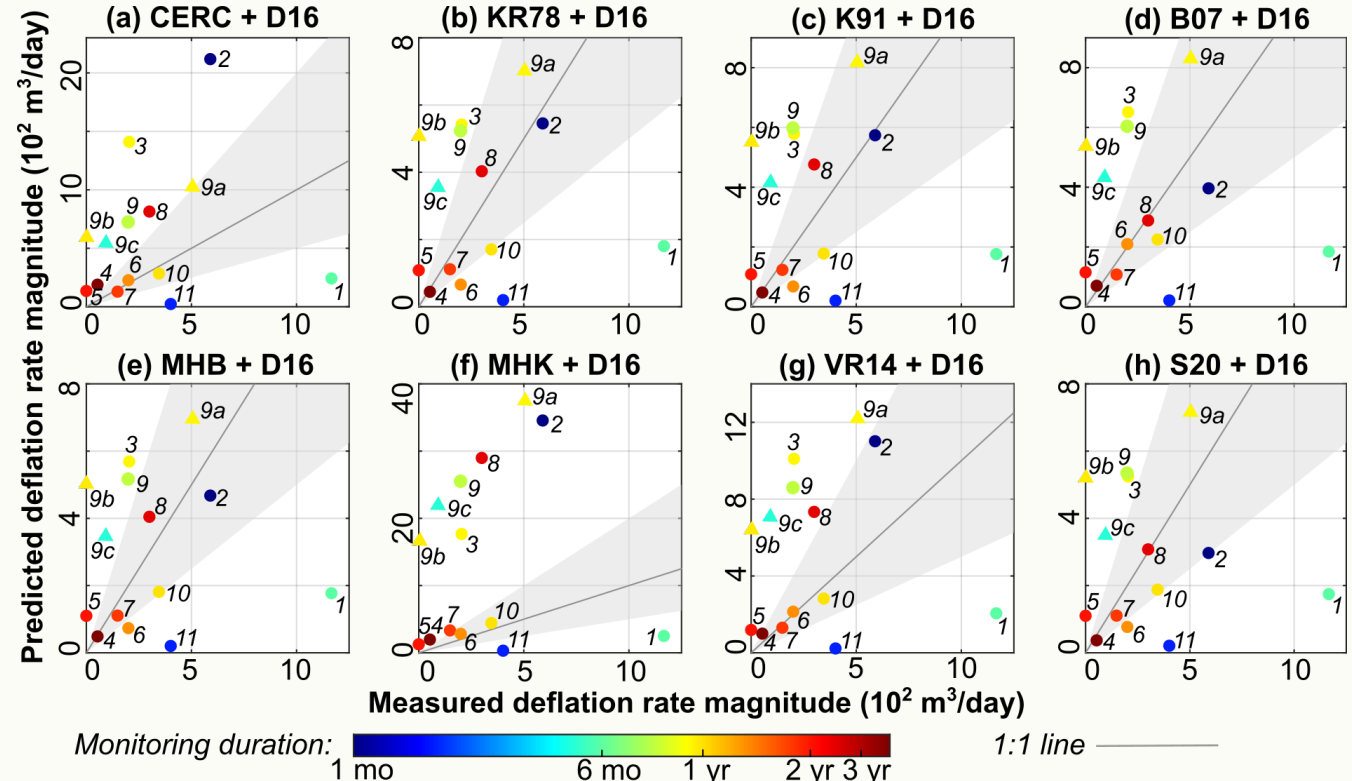

# Validation

- Eight longshore transport formulations were evaluated for relative performance.
- Cross-shore transport was calculated using the method of Dronkers (2016) as implemented by Hudson et al. (2021).
- Error between measured and calculated deflation rates was determined for 11 historical nearshore berm sites.
- Best-performing method applies the longshore transport formula of Shaeri et al. (2020) and the cross-shore transport formula of Dronkers (2016; abbreviated S20+D16 at right).
  - Maximum |percent error| of 167%
  - Average |percent error| of 72%.
  - Low sensitivity to grain size uncertainty.
  - Low sensitivity to beach slope uncertainty.

- 10: Coos Bay, OR (1988)
- 11: North Head, WA (2018)

# Summary

## FY21 Major Advances in Capability

- Cross-shore transport added to longshore-based method developed in FY20.
- Significant increase in scope of validation.
- Methods documented in detail and available to the public.

## FY21 Major Products & Collaborations

- 1 journal article published in *Journal of Waterway, Port, Coastal, and Ocean Engineering*.
- 1 CIRP TD in May 2021.

---

## FY22 Products/Advances

- Methodology will be implemented within Sediment Mobility Tool (SMT).
